

Canine Parvovirus in Dogs - Epidemiology Update

2016

Canine Parvovirus (Parvo) in Dogs in Los Angeles County

1st quarter

Volume 2, Issue 1

There were new 84 cases of canine parvovirus in dogs reported in the first quarter of 2016, with 56 (67%) being confirmed by testing and the remaining being suspected. This is significantly fewer than the 133 cases reported in the first quarter of 2015. The median age of the cases was 4.5 months, with a range of 5 weeks to 2 years. Parvo cases have exhibited a seasonal trend since surveillance began in 2007, with peaks occurring in the spring and autumn months.

A total of 44 reports (52% of total) in the first quarter of 2016 were from animal shelters. The majority (78%) were diagnosed within the first 4 days in the shelter (usually upon admission) indicating **they had been infected in the community before intake, not in the shelter.**

Of the community-acquired cases 12 (17%) were in from the Antelope Valley area, including the cities of Lancaster and Palmdale. Of the 27 cases in the City of Los Angeles, 7 cases (26%) were in 90011. Historically, cases have clustered in the Antelope Valley, Lynwood, Compton, Pacoima, and Wilmington.

Why does Public Health Track Canine Parvovirus in dogs?

Canine parvovirus does not make people sick. However, parvo cases in dogs serve as markers for areas where access to veterinary services is lower. Vaccination against parvo in dogs is a core part of basic veterinary care. Veterinary professionals play a significant role in protecting the public's health work by preventing, detecting and treating zoonotic diseases in animals (reducing risk of spread to people), educating the public on animal bite prevention, and encouraging a healthy lifestyle (such as preventing dog and human obesity through encouragement of dog walking).
